## Variance and Inbreeding

Peter von Rohr

2020-11-06

#### Assumption

- ▶ Variance of breeding value  $u_i$ :  $var(u_i) = (A)_{ii}\sigma_u^2$
- ▶ Diagnoal elements of numerator relationship matrix A

$$(A)_{ii}=(1+F_i)$$

where

 $F_i$  inbreeding coefficient of animal i  $\sigma_u^2$  genetic additive variance

- ▶ The higher F<sub>i</sub>, the higher the similarity, the higher the variance
- $\rightarrow$  Contradiction?

## Variance and Inbreeding

- Relationship between variance and inbreeding
- ▶ How does inbreeding affect the genetic variance?
- How do we get inbreeding in a population?
- → Population separates into different lines

### Population with Inbreeding

#### Assumptions

- N individuals
- self-fertilizing, shedding constant rate of eggs and sperm
- at a given locus: alleles in base population are non-identical by descent
- N individuals produce 2N gametes (eggs and sperm) at constant rate
- ▶ probability that a pair of gametes taken at random carry identical alleles: 1/2N
- probability corresponds to the inbreeding coefficient (F)

## Inbreeding Coefficient

▶ In generation 1:

$$F_1=rac{1}{2N}$$

- second generation
  - ▶ either de-novo match of alleles or
  - ▶ the same alleles from generation 1

$$F_2 = \frac{1}{2N} + (1 - \frac{1}{2N}) * F_1$$

▶ new variable  $\Delta F = \frac{1}{2N}$ , then

$$F_2 = \Delta F + (1 - \Delta F) * F_1$$

## Inbreeding Coefficient II

- ▶ Generation t:  $F_t = \Delta F + (1 \Delta F) * F_{t-1}$
- ▶ Solving for  $\Delta F$

$$\Delta F = \frac{F_t - F_{t-1}}{1 - F_{t-1}}$$

Panmicitic Index P = 1 - F

$$\frac{P_t}{P_{t-1}} = 1 - \Delta F$$

$$P_t = (1 - \Delta F)^t * P_0 \text{ with } P_0 = 1$$

$$F_t = 1 - (1 - \Delta F)^t$$

## Variance of Gene Frequency

- ▶ Allele frequencies (p and q) no longer constant in lines  $\rightarrow$  variation
- ightharpoonup Variance of change of q (same for p)

$$\sigma_{\Delta q}^2 = \frac{p_0 q_0}{2N} = p_0 q_0 \Delta F$$

▶ Variance of q (same for p)

$$\sigma_a^2 = p_0 q_0 F$$

#### Genotype Frequencies

- Average genotype frequency of homozygotes across all lines:  $q^2$
- Definition of variance

$$\sigma_q^2 = \bar{q^2} - \bar{q}^2$$

where  $\bar{q}$  is the mean allele frequency across all lines and hence is the same as  $q_0$  in the base population

Therefore

$$\bar{q^2} = q_0^2 + \sigma_q^2 = q_0^2 + p_0 q_0 F$$

### Genotype Frequencies II

Table 1: Genotype Frequencies for a bi-allelic locus, expressed in terms of inbreeding coefficient  ${\it F}$ 

Genotype	Original Frequencies	Changes due to inbreeding
$ \begin{array}{c} A_1 A_1 \\ A_1 A_2 \\ A_2 A_2 \end{array} $	$p_0^2$ $2p_0q_0$ $q_0^2$	$+p_0q_0F$ $-2p_0q_0F$ $+p_0q_0F$

# Changes of Mean Value

Table 2: Derivation of Inbreeding Depression

Genotype	Frequency	Value	Product
$ \begin{array}{c} A_1 A_1 \\ A_1 A_2 \\ A_2 A_2 \end{array} $	$egin{aligned} ar{p}^2 + ar{p}ar{q}F \ 2ar{p}ar{q} - 2ar{p}ar{q}F \ ar{q}^2 + ar{p}ar{q}F \end{aligned}$	a d — a	$(\bar{p}^2 + \bar{p}\bar{q}F)a$ $(2\bar{p}\bar{q} - 2\bar{p}\bar{q}F)d$ $-(\bar{q}^2 + \bar{p}\bar{q}F)a$

### Inbreeding Depression

$$M_F = (\bar{p}^2 + \bar{p}\bar{q}F)a + (2\bar{p}\bar{q} - 2\bar{p}\bar{q}F)d - (\bar{q}^2 + \bar{p}\bar{q}F)a$$

$$= a(\bar{p} - \bar{q}) + 2d\bar{p}\bar{q} - 2d\bar{p}\bar{q}F$$

$$= a(\bar{p} - \bar{q}) + 2d\bar{p}\bar{q}(1 - F)$$

$$= M_0 - 2d\bar{p}\bar{q}F$$

## Changes of Variance

- Only additive locus
- ► Within line: as before

$$V_{\bar{G}} = 2(\bar{pq})a^2$$
  
=  $2p_0q_0(1-F)$   
=  $V_G(1-F)$ 

▶ New variance component: between line

$$var(M) = \sigma_M^2 = 4a^2\sigma_q^2 = 4a^2p_0q_0F = 2FV_G$$

## Summary

Table 3: Partitioning of the variance in a population with inbreeding coefficient  ${\sf F}$ 

$\begin{tabular}{lll} Source & Variance \\ \hline Between lines & $2FV_G$ \\ Within lines & $(1-F)V_G$ \\ Total & $(1+F)V_G$ \\ \end{tabular}$			
Within lines $(1-F)V_G$	Source	Variance	
	Within lines	$(1-F)V_G$
